This Spotlight on research areas is for informational purposes only. The information contained in this Spotlight does not constitute agency policy, guidance, or recommendations or legally enforcement requirements. It is also not meant to indicate that the identified topics are areas for regulation. It is not intended to propose or implement policy changes regarding regulation of any of the digital health topic areas described within. The references cited herein are for informational purposes only and should not be construed as endorsements. Utilizing the information presented in this Spotlight does not constitute compliance with any requirements of the Federal Food, Drug, and Cosmetic Act, or any other applicable law. We hope that this Spotlight on research areas is helpful to stakeholders interested in advancing the science in the ever-evolving digital health landscape.

Digital health is enabling the rapid evolution of the health care system towards an increasingly patientcentered model where care is available outside of traditional hospital and clinical environments. This is blurring the lines that used to separate episodes of care from daily life. The coronavirus disease 2019 (COVID-19) pandemic and associated public health emergency accelerated the adoption of innovative digital health technologies (DHTs)¹ and health care delivery models, further establishing telecare as a staple in modern health care that is supplementing—and disrupting—existing care delivery paradigms. DHTs are increasingly ubiquitous, with many individuals using one or more consistently through the day. DHTs can include both medical devices and consumer products. The power and ubiquity of DHTs and general-purpose computing platforms that enable telecare continue to increase, providing more opportunities for evidence-based digital health products with the potential to support more equitable access to health care, improve patient outcomes, and promote public health.

Digital health encompasses many components critical to the future of health care. To enable connected care and improved public health, stakeholders should carefully consider the importance of wireless connectivity, cybersecurity, and interoperability. DHTs can help real-world data (RWD) and real-world evidence (RWE)² facilitate regulatory, health care, and other types of decision-making. With this, however, comes the need for further exploration into the potential impact of using DHTs, taking traditional human factors a step further and examining the cognitive and neurological effects on users like patients and health care providers. Furthermore, digital health offers the potential to reach many underserved populations and improve the health care individuals receive. Stakeholders across the digital health ecosystem should approach development, implementation, and advancement of digital health solutions thoughtfully to promote health equity³ and user trust in new technologies.

The U.S. Food and Drug Administration (FDA) is committed to continuing to play an integral role in the health care ecosystem as it evolves, helping assure that DHTs that meet the definition of device⁴ are safe and effective. The FDA issues appropriate requirements and develops policies for areas of great importance to public health, like medical device software as well as DHTs used in clinical studies, healthcare and wellness. To foster responsible and high-quality innovation in digital health, the FDA's Center for Devices and Radiological Health (CDRH) established the Digital Health Center of Excellence (DHCoE) in September 2020. The DHCoE works to empower digital health stakeholders by promoting awareness, transparency, and consistent application of digital health regulatory paradigms; and fostering

digital health-focused collaborations. In alignment with CDRH's regulatory science priorities⁵ and the FDA's focus areas of regulatory science⁶, efforts within the DHCoE are focused on improving the safety, effectiveness, and quality of medical products. CDRH is an active contributor in the digital health space, hosting multiple public meetings^{7,8,9,10}, listening sessions^{11,12}, and Patient Engagement Advisory Committee meetings¹³, as well as providing resources^{14,15} for the stakeholder community. Current CDRH research programs¹⁶ focus on the areas highlighted in this document. CDRH's involvement in the digital health ecosystem extends into collaborative communities as well, where the FDA participates in a variety of communities with digital health focus areas.¹⁷

This document is intended to advance digital health regulatory science by encouraging discussions and stakeholder collaborations throughout the health care ecosystem and beyond. Patients, researchers,

health care providers, medical product manufacturers, technology companies, standards organizations, and others play integral roles in advancing digital health. Collaborations can take many forms, with various levels of involvement by individual stakeholders, which can include the FDA. Alignment and partnerships can help focus efforts on the research and application of DHTs. Innovation in digital health can continue, with the goal of promoting the use of safe and effective medical products that have the potential to improve patient outcomes and public health.

This document does not initiate a call for proposals or carry funding implications. Instead, it is meant to highlight important scientific research areas identified by stakeholders internal and external to the FDA. These areas are divided into three categories: advancing patient engagement, leveraging connectivity, and improving health care through software (although these are not intended to be exhaustive). Topic areas are further broken down into near-term and longer-term categories depending on whether there are longer-term efforts that may help to advance the field. We anticipate that advances in digital health will continue to occur rapidly and prompt new areas of interest for regulatory science research in the future.

Advancing Patient Engagement

DHTs can help seamlessly integrate individuals as proactive agents of their health care and wellness, potentially expanding access to and quality of care. Thoughtful and consistent engagement with patients can help fully realize the potential of this technology. DHTs can collect patient-generated health data (PGHD) to help provide critical information on personal behavior, physiology, and preferences. The information gleaned from patients can help shape future medical products and care paradigms. Ongoing FDA efforts in patient science & engagement¹⁸, human-device interactions¹⁹, and medical extended reality²⁰ have highlighted the importance of the patient voice in medical product development.

Patient-Generated Health Data

PGHD can be used to complement data collected during clinical visits to form a more complete picture of a person's health status.²¹ DHTs, including wearable consumer products or medical devices, mobile applications, software, and patient-led registries, are common sources of this type of RWD. PGHD, including biometric data, symptoms, and patient-reported outcomes, can be used in patient monitoring, diagnosis and prognosis, shared decision-making, and assessment of patient

¹⁸ CDRH Patient Science and Engagement Program. U.S. Food and Drug Administration (2021). Available at <u>https://www.fda.gov/about-fda/center-devices-and-radiological-health/cdrh-patient-science-and-engagement-program</u>.

investigations.

Advances in computing and display technologies have fostered rapid growth in the availability of augmented reality (AR), virtual reality (VR), and mixed reality technologies. Accompanying these advances is the increased interest in the use of this technology outside of the gaming and entertainment industries, moving into the development of medical extended reality (MXR) devices. Both health care professionals and patients may be primary users of MXR devices, with applications in surgical, diagnostic, and therapeutic spaces.

MXR-Related Research Areas

Leveraging Connectivity

Intrinsic to DHTs is connectedness—to the Internet, health care networks, and other DHTs. This connectedness can improve access to care, quality of care, and system efficiency. Wireless connectivity can enable remote patient monitoring, remote operation of medical devices (for example, telesurgery or device programming), and data sharing between platforms. These functions are critical in underserved areas where they can help expand access to care. The exchange and potential use of information across connected systems warrants coordination across systems to minimize risk to an individual and the ecosystem, as well as to ensure efficiency within the system. With the ever-increasing connectedness in health care comes cybersecurity and interoperability concerns. The FDA is actively engaged in both internal and external efforts to help mature cybersecurity²², interoperability²³, and wireless connectivity²⁴ efforts.

Cybersecurity

With the connected nature of digital health, increased exposure to cybersecurity threats is introduced. Management and prevention of cybersecurity threats is important to maintain patient safety with this increasing level of connectedness. Establishing and maintaining cybersecurity is a collective undertaking between manufacturers, patients, health care facilities, providers,

lifecycle, from development through post-market applications.²⁷ Interoperability not only applies to DHTs, but laboratory and electronic health record data and semantics as well.

Research focused on interoperability can catalyze innovation to address many health care issues from public health emergencies to monitoring of patient safety. Rapid integration of data from different sources can help during the development and deployment of novel health care solutions with applications like remote medical device control and intelligent interaction between patient monitoring devices, all working to improve clinical outcomes and patient safety.

Interoperability-Related Research Areas

Wireless Connectivity

Medical devices increasingly rely on wireless connectivity, including Wi-Fi, Bluetooth, and 5G, especially as health care shifts from the clinic to the patient. Wireless technologies that can be used in medical devices have diverse characteristics, including the communication range, access-right type to the radiofrequency spectrum (for example, licensed vs. unlicensed), support for mobility, and network management mode (for example, 5G network centrally controlled by a network operator vs. user-controlled Wi-Fi network).

Connectivity-Related Research Areas

Improving Health Care through Software

As the reliance on connected and smart products increases, the role of software is also growing. It is a critical component of the digital world, especially within digital health where consumer software and medical device software functions support the evolving health care ecosystem. Innovative uses of software in the manufacturing of medical products can help improve quality and efficiency. Further applications of novel software include the integration of artificial intelligence and machine learning (AI/ML)²⁸ into medical imaging and diagnostics. Contributing to the advances within the field, ongoing FDA efforts have included additive manufacturing^{29,30}, AI/ML³¹, and digital imaging^{32,33}.

Advanced Manufacturing Technologies

Innovative technologies or the innovative application of existing technologies and processes is gaining traction in the manufacturing of medical products. When applied, advanced manufacturing offers the opportunity to improve quality, performance, and compliance of medical products while encouraging innovation in the medical technology space.

Typical methods of advanced manufacturing include additive manufacturing and intelligent manufacturing (for example, automation and the use of AI when streamlining production). Successful implementation of advanced manufacturing techniques can potentially aid in addressing medical product shortages, improve medical product supply chain resilience, and enhance domestic medical product production agility.³⁴

Advanced Manufacturing-Related Research Areas

Artificial Intelligence and Machine Learning

DHTs harnessing the power of AI/ML have the potential to transform health care, from optimizing workflows to improving diagnostic capabilities.³⁵ When used as a medical device or in a medical device, this rapidly progressing field can assist health care providers and improve patient care. AI/ML can also be implemented to improve the production and quality system processes in medical product manufacture or the performance of medical devices (for example, optimizing the acquisition of medical imaging data). The nature of the design process of many AI/ML algorithms gives them the capability to learn from real-world experience to improve their performance or to adapt to changing clinical conditions.

Digital Imaging

Digitization of medical imaging in diagnostic and therapeutic applications across many clinical areas has the potential to improve the quality and efficiency of care. Traditional radiology modalities are currently harnessing the power of AI/ML to enhance tasks like lesion detection, computer-aided-diagnosis, and image reconstruction or segmentation. Digital pathology is an emergent area within digital health that visualizes, analyzes, and interprets digitized specimen slides, typically in a diagnostic application. Additionally, clinical areas like ophthalmology and dermatology are also rapidly integrating AI/ML into workflows to enhance tasks like informing diagnoses. Overall, digital imaging is an important component of health care of the future. Since digital imaging relies heavily on AI/ML, many of the research gaps presented in the AI/ML section of this document are also relevant.

Digital Imaging-Related Research Areas
